The basic principle

Relationship between precipitation and runoff

The water catchment area as a unique system, in which the precipitation are transformed into the runoff!

- input: precipitation, temperature
- output: runoff

Which hydrological model?

- various ongoing researches are there on topics like which model will give more compatible results compared to P-R relations
- HSPF, HSPEXP+, TOPMODEL, HBV-96, WFLOW Py(distributed HBV), MIKE-SHE, SWAT, SWMM, RS Minerve...

HBV-light & PEST

HBV-light: <http://www.geo.uzh.ch/en/units/h2k/services/hbv-model/>

PEST: <http://www.pesthomepage.org/>

HBV - Hydrologiska Byråns Vattenbalansavdelning (Hydrological Agency Water Balance Department)

- The HBV model (Bergström, 1976, 1992) is a rainfall-runoff model, which includes conceptual numerical descriptions of hydrological processes at the catchment scale. The general water balance can be described as

$$P - E - Q = \frac{d}{dt} [SP + SM + TZ + UZ + LZ + lakes]$$

Where

P = precipitation

E = evapotranspiration

Q = runoff

SP = snow pack

SM = soil moisture

TZ = storage in soil top zone (introduced in HBV-light) UZ = upper groundwater zone storage

LZ = lower groundwater zone storage

lakes = lake volume

Source: <http://www.smhi.se/forskning/forskningsomraden/hydrologi/hbv-1.1566>

Semi-distribution

Subdivides a large problem into smaller, simpler parts with unique characteristic

- Elevation zones
- Vegetation zones

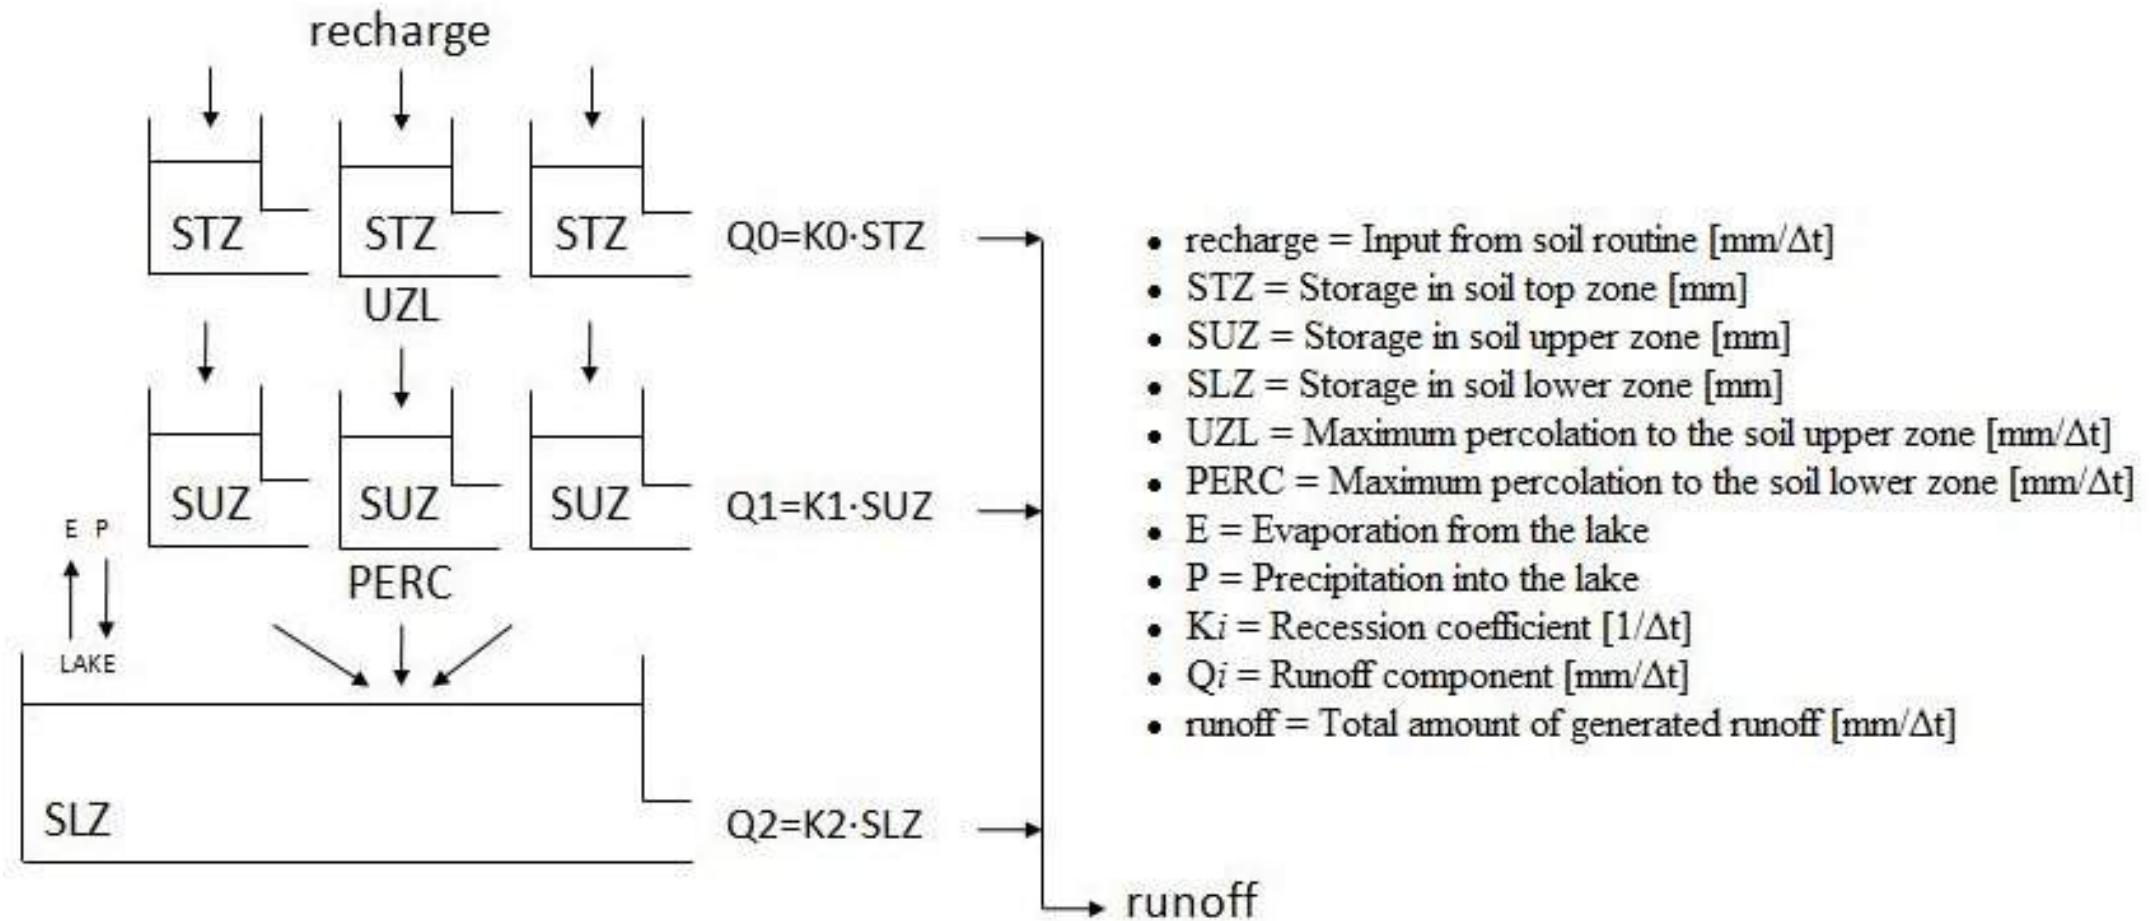

HBV overview

- The HBV model is a **simple multi-tank-type model** for simulating runoff.
- Rainfall and air temperature data as well as estimated potential evaporation data based on the American Society of Civil Engineers Penman–Monteith method are inputs to the model, which consists of four commonly used routines: snow; soil moisture; response; and routing.

Picture: Help HBV-light – An Overview of the HBV Model

Model of Computed Runoff

Equations Overview

$$\text{melt} = CFMAX(T(t) - TT)$$

$$\text{refreezing} = CFR \cdot CFMAX(TT - T(t))$$

$$\frac{\text{recharge}}{P(t)} = \left(\frac{SM(t)}{FC} \right)^{BETA}$$

$$E_{act} = E_{pot} \cdot \min\left(\frac{SM(t)}{FC \cdot LP}, 1 \right)$$

$$Q_{GW}(t) = K_2 \cdot SLZ + K_1 \cdot SUZ + K_0 \cdot \max(SUZ - UZL, 0)$$

$$Q_{sim}(t) = \sum_{i=1}^{MAXBAS} c(i) \cdot Q_{GW}(t - i + 1)$$

$$\text{where } c(i) = \int_{i-1}^i \frac{2}{MAXBAS} \left| u - \frac{MAXBAS}{2} \right| \frac{4}{MAXBAS^2} du$$

$$P(h) = P_0 \left(1 + \frac{PCALT(h - h_0)}{10000} \right)$$

$$T(h) = T_0 - \frac{TCALT(h - h_0)}{100}$$

$$E_{pot}(t) = \left(1 + C_{ET} \left(T(t) - T_M \right) \right) E_{pot, M}$$

$$\text{but } 0 \leq E_{pot}(t) \leq 2 E_{pot, M}$$

Catchment Parameters

| Name | Unit | Valid range | Default value | Description | See also |
|--------|--------------------------------|-------------|---------------|---|--|
| PERC | mm/ Δt | [0,inf) | 1 | threshold parameter | Response Function |
| Alpha | - | [0,inf) | 0 | non-linearity coefficient | Response Function |
| UZL | mm | [0,inf) | 20 | threshold parameter | Response Function |
| K0 | 1/ Δt | [0,1) | 0.2 | storage (or recession) coefficient 0 | Response Function |
| K1 | 1/ Δt | [0,1) | 0.1 | storage (or recession) coefficient 1 | Response Function |
| K2 | 1/ Δt | [0,1) | 0.05 | storage (or recession) coefficient 2 | Response Function |

What is PEST?

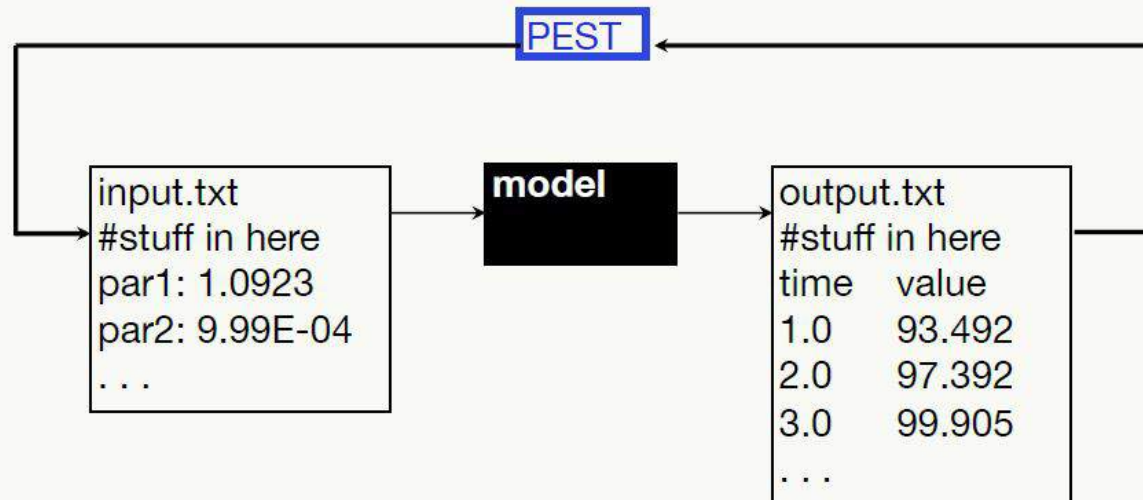

Written by John Doherty/Watermark Numerical Computing

Model-independent parameter estimation code

Writes ASCII model input, **reads** ASCII model output

Takes control of a model and runs it many, many times

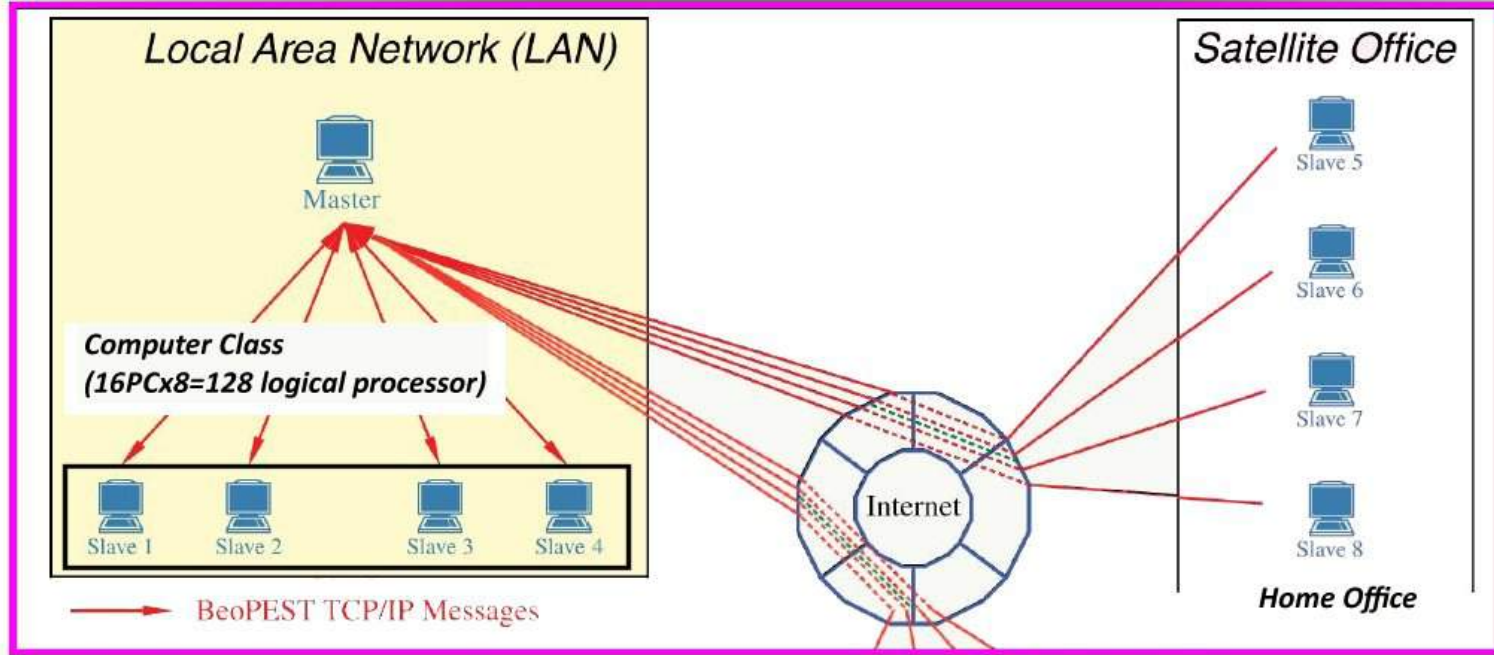

Pleasingly parallel

Parameter Estimation and
Uncertainty Analysis

- * parameter are estimated on the basis of past events
- * some of them cannot be estimated uniquely

BeoPEST, PEST++ are tools for model calibration and uncertainty analysis

Need to launch remote slave processes

Each slave needs model files

Model Calibration

The calibration of the model is usually made by manual try and error technique (Bergström, 1992).

The coefficient of efficiency, R_{eff} , is normally used for assessment of simulations by the HBV model.

$$R_{eff} = 1 - \frac{\sum (Q_{Sim}(t) - Q_{Obs}(t))^2}{\sum (Q_{Obs}(t) - \bar{Q}_{Obs})^2}$$

Different criteria can be used to assess the fit of simulated runoff to observed runoff:

- visual inspection of plots with Q_{sim} and Q_{obs}
- accumulated difference
- statistical criteria

R_{eff} compares the prediction by the model with the simplest possible prediction, a constant value of the observed mean value over the entire period.

$R_{eff} = 1$ Perfect fit, $Q_{Sim}(t) = Q_{Obs}(t)$

$R_{eff} = 0$ Simulation as good (or poor) as the constant-value prediction

$R_{eff} < 0$ Very poor fit

Note:

- the calibration period should include a variety of hydrological events
- normally 5 to 10 years sufficient to calibrate the model
- validation: test of model performance with calibrated parameters for an independent period

1. Why use a P-R modeling?

- for education
- for decision support
- for data quality control
- for water balance studies
- for drought runoff forecasting (irrigation)
- for fire risk warning
- for runoff forecasting/prediction (flood warning and reservoir operation)
- for what happens if' questions

2. Why use a P-R modeling?

- to compute design floods for flood risk detection
- to extend runoff data series (or filling gaps)
- to compute design floods for dam safety
- to compute energy production
- to investigate the effects of land-use changes within the catchment
- to simulate discharge from ungauged catchments
- to simulate climate change effects

Designed Flood Predictions

- based on flood event 2007 (50 year return period)
[24 hour](#) Precipitation Event for Q10, Q20, Q50, Q100, Q200 and Q500
- based on flood event 1990 and 1998 (100 year return period)
[48 hour](#) Precipitation Event for Q10, Q20, Q50, Q100, Q200 and Q500
